The thiocyanates are more stable than the cyanates, and remain without decomposition in aqueous solution for an indefinite period. Ammonium thiocyanate $\text{NH}_4 \cdot \text{S} \cdot \text{C} \cdot \text{N}$: N is formed on treating a solution of hydrogen cyanide with yellow ammonium sulphide; a more convenient method of preparation is to heat carbon bisulphide with alcoholic ammonia: $\text{CS}_2 + 4\text{NH}_3 = \text{NH}_4 \cdot \text{S} \cdot \text{CN} + (\text{NH}_4)_2\text{S}$. It is a crystalline substance, soluble in water and in alcohol, which melts at about 1500. On heating to 1700-1800 it undergoes an intramolecular rearrangement similar to that of ammonium cyanate, yielding thiocarbamide (p. 183). Alkyl thiocyanates $\text{R} \cdot \text{S} \cdot \text{C} \cdot \text{N}$ in which an alkyl radicle replaces the metal, may be prepared by two different methods, which clearly show their constitution: firstly by the action of alkyl halides, or alkyl esters of inorganic salts, such as metallic...
